SUBJECT: Mechanical Properties of Inconel X Sheet at +78°, -100, -320, and -423° F

An evaluation of the properties of Inconel X sheet at ambient and cryogenic temperatures was undertaken due to an increased interest in the substitution of a high strength/density material with favorable low temperature properties for type 321 annealed stainless steel in the production of thrust rings, brackets, etc. Inconel X, a heat-treatable nickel-base alloy, offered many attractive features such as availability in many forms, good welding characteristics, good corrosion resistance, and moderately high tensile strengths. In order to ascertain the possible application of Inconel X at cryogenic temperatures, the mechanical properties (F_{ty} , F_{tu} , e , and notched/unnotched tensile ratios) of the base metal and resistance spot weld properties of Inconel X to 301 XPH stainless steel were determined at +78°, -100, -320, and -423° F. Report MRG-134, "Evaluation of Inconel X to 301 Stainless Steel Resistance Spotwelds at 78° F and -423° F", presented data which showed that reliable, high strength resistance spot welds were obtained with Inconel X - 301 XPH stainless steel sheet materials at both room and very low (-423° F) temperatures.

In the present report Table 1 gives the chemical composition limits of Inconel X and Table 2 the typical mechanical properties of annealed and heat treated material in various available forms (sheet, plate, rod and bar, strip, castings, tubing, and wire). Table 3 presents data generated by the Materials Research Group on 0.063-inch Inconel X sheet, solution treated and aged, as a function of temperature (78°, -100, -320, and -423° F).

The relatively high yield strength (118 ksi, 0.2-percent offset at 78° F) of the solution treated and aged Inconel X sheet makes this material look most favorable in comparison to 321 annealed stainless steel which has a design allowable yield strength of 30 ksi. Since the densities of these two materials are nearly the same (0.29 lb/in.³ for 321 and 0.30 lb/in.³ for Inconel X), the strength-to-weight ratio of Inconel X is at least three times that of type 321 CRES. A significant increase in yield strength is also realized at lower temperatures (134 ksi at -423° F). The Inconel X sheet material also exhibits high ultimate tensile strengths (174 ksi at 78° F and 233 ksi at -423° F), with very good ductility (25.0 to 31.0 percent) as measured by elongation at all testing temperatures. The proportional limit is 95 ksi at 78° F and higher at reduced temperatures. The notched/unnotched ratio, a criterion of brittle fracture, is somewhat low (0.85 at lower temperatures); however, its metallurgical similarity to K-Monel which has proved satisfactory for cryogenic applications in the Atlas missile system (LOX lines, valves, ducts, etc.) warrants further consideration and resulting development of Inconel X

for subzero temperature use. The fact that the notched tensile strength significantly increases with reduction in temperature (168 ksi at 78° F to 200 ksi at -423° F) is indicative of favorable crack resistance at low temperatures.

Several specimens of Inconel X in the as-received condition (annealed, from 1900 to 2100° F) were tested, but the low yield strength (47 ksi at 78° F) practically eliminates the use of Inconel X in this condition except in those cases where an aging treatment is not practicable. Normal heat treatment of Inconel X for applications at 1100° F or less is annealing (1900 to 2100° F) followed by aging (1300° F/20 hr, and air cooled).

Present data indicate that the favorable subzero mechanical properties of the base metal and the reliable, high-strength resistance spot welds (to 301 CRES) of Inconel X makes it a candidate material to replace type 321 CRES for thrust ring applications.
